

System Brief: Bessieres

PHYSICAL DATA

Bessieres was the name applied to the DM+36 2147 star system by the French captain of the ESA scout ship that first visited it. The star lies 8.257 light years from Sol, but due to the distance limitations of stutterwarp drive, travel is 11.650 light years and requires two jumps. There are three neighbors accessible by stutterwarp travel: Nyotekundu, Neubayern, and Ross 128.

The binary system contains two stars, Bessieres A, and an unseen companion, Bessieres B, orbiting at an average of 38 au. The primary is a M2V star, with a radius of 0.464 Sol and a mass of 0.420 Sol. Its average luminosity is 0.0268 Sol, with a Stellar Effective Temperature of 3220°K, and an absolute magnitude of 10.49. The companion is a M0V star with a radius of 0.540 Sol and a mass of 0.48 Sol. Average luminosity is 0.04 Sol, with a Stellar Effective Temperature of 3500°K, and an absolute magnitude of 13.

Only the primary has a planetary system; the companion has no planets, and no bodies orbit the combined system. The life zone of the primary ranges from 0.118 au to 0.237 au; all system bodies are in the outer zone the life zone of the companion ranges from 0.144 au to 0.290 au.

TRAVEL DATA

The planetary system of the primary, Bessieres A, consists of four planets, thirteen satellites, and an asteroid belt. The stellar 0.0001 g-gradient of the primary is located at 1.588 au, with a 0.1 g-gradient at 0.051 au. Planets I – III are within the stellar threshold; planet IV and the asteroid belt are outside. Stutterwarp discharge is possible at the following system bodies: I, II, II, IV, and IV d; in addition to the primary. Bessieres B has no planetary system. The stellar 0.0001 g-gradient of the primary is located at 1.697 au, with a 0.1 g-gradient at 0.054 au. Primary discharge is at IV d, where a French outpost is located, or at IV for ships not calling at the outpost.

Bessieres A I

Planet is a Failed Core body orbiting at 0.40 au with no satellites. Travel distance within threshold is 1.19 au. Stutterwarp discharge is possible from an altitude of 3,478 km.

Bessieres A II

Planet is Failed Core body orbiting at 0.60 au with no satellites. Travel distance within threshold is 0.99 au. Stutterwarp discharge is possible from an altitude of 12,504 km

Bessieres A III

Planet is Gas Giant body orbiting at 1.02 au with eight satellites. Travel distance within threshold is 0.57 au. Stutterwarp discharge is possible from an altitude of 25,157 km. Satellites consist of five rings, two ice balls, and one rock. Stutterwarp discharge is not possible at any satellites.

Bessieres A IV¹

Planet is Gas Giant body orbiting at 2.14 au with five satellites. Planet is located beyond threshold. Stutterwarp discharge is possible from an altitude of 487,420 km. Satellites consist of two rings, a

System Brief: Bessieres

chunk, a failed core, and an ice ball. Stutterwarp discharge is possible at IV d from an altitude of 4,201 km. A French outpost is located on IV d, and serves as a way station, providing fuel mined from the ice ball at IV e.

Bessieres A V

Orbit V is empty.

Bessieres A VI

Asteroid belt is present in orbit VI. Stutterwarp discharge is not possible.

Bessieres B I

Orbit I is empty.

Position: Inside indicates body orbits within the stellar 0.0001G gradient.
 T-Travel: The distance that must be traveled within the stellar 0.0001G gradient to reach the body.
 0.1G: The distance of the 0.1G gradient from the core of the body.
 0.1G Altitude: The distance of the 0.1G gradient above the surface of the body. A result of "none" indicates that a usable 0.1G gradient is not available and discharge cannot occur at the body.

Notes

France maintains an outpost since 2145 on Bessieres IV d.

Values for all planets and satellites are unofficial, except that gravity of outpost is 0.58G (2300AD Director's Guide / Colonies of Earth table).
